1. In a data communications system, a method of interleaving data into a single interface from a plurality of channels supporting a plurality of data rates, the method comprising the steps of:

polling each channel in the data communications system to determine if the channels are active, the polling order determined according to a state machine, the state machine comprising at least one state for each data rate supported by the plurality of channels; and

interleaving data from the active channels into the single interface according the states of the state machine.

- 2. The method of claim 1 further comprising the step of changing the data rate of at least one of the plurality of channels.
- 3. The method of claim 1 wherein the state machine further comprises at least four states.
- 4. The method of claim 1 further comprising the step of buffering the data.
- 5. The method of claim 1 further comprising the step of enabling one or more channels.
- The method of claim 1 further comprising the step of disabling one or more channels.
- 7. The method of claim 1 wherein the data channels comprise dissimilar physical layers.

- 8. The method of claim 1 wherein the data communications network comprises a synchronous optical network (SONET).
 - 9. The method of claim 1 wherein the plurality of data rates comprise digital signal level zero (DS0), digital signal level one (DS1), digital signal level two (DS2), and digital signal level three (DS3).
 - 10. For use in a data communications network, a reconfigurable transmit mechanism supporting the interleaving of data from data channels having dissimilar data rates, comprising:

sequential circuit means for polling each data channel to identify active data channels; and

means for interleaving data from the active data channels into a single interface for transmission in the data communications network.

- 11. The mechanism of claim 10 further comprising means for reconfiguring the data channels for different data rates.
- 12. The mechanism of claim 10 further comprising means for buffering the data prior to interleaving.
- 13. The mechanism of claim 10 wherein the data communications network further comprises a SONET.
- 14. The mechanism of claim 10 further comprising means for enabling/disabling channels.

- 15. A data communications routing circuit supporting the interleaving of data from a plurality of data channels having dissimilar data rates, comprising means for:
- (a) identifying one or more first active data channels from among a plurality of channels of a first data rate;
- (b) inviting the one or more first active channels to send data at a first data rate;
- (c) identifying one or more next active data channels from among a plurality of channels of a next data rate; and
 - (d) inviting the one or more next active channels to send data at a next rate.
- 16. The routing circuit according to claim 15 further adapted for the reiteration of steps (c) and (d) for at least three dissimilar data rates.
- 17. The routing circuit according to claim 15 further adapted for the reiteration of steps (c) and (d) for five or more dissimilar data rates.
- 18. The routing circuit of claim 15 further comprising means for reconfiguring channels for different data rates.
- 19. The routing circuit of claim 15 wherein the data communications network further comprises a SONET.
- 20. The routing circuit of claim 15 further adapted for dynamically activating/deactivating one or more channels.
